Not illustrated. 1997-06 Excerpt: . distribution of vertical and horizontal hydraulic conductivity (K_z and K/J), (3) distribution of storage coefficients, and (4) flux at all boundaries. Flux, as used in this report, is the volumetric rate of flow per unit area entering or leaving the cross section. Physical dimensions of the cross section were determined from well logs, aerial photographs, and transit-stadia surveys. The model grid consisted of 7 layers, 1 row, and 43 columns (fig. 16). Model layers were designed to approximate the extent and occurrence of sand and clay layers in the alluvial aquifer. Distribution of K_h was estimated on the basis of slug-test results and was modified slightly during model calibration. Distribution of K , and storage coefficients for some layers were estimated during calibration. Specified flux-boundary conditions were used and included the special case of no flow (fig. 16). No-flow boundaries were specified for the lower and lateral boundaries of the cross section. The use of no-flow conditions at the lateral boundary under the stream was based on the assumption that the ground-water flow system is symmetric about the stream channel.
